Algorithmic Fairness, Accountability, and Ethics, Spring 2023, IT University of Copenhagen

Mandatory Assignment 2 v1.1

Germans Savcisens, Camilla Jung Westermann

- Hand-out: March 20, 2023
- Hand-in: April 11, 2023 at 23:59
- What to hand-in: A report as a pdf summarizing the main findings, max. 3 pages, including plots (that support your story. You do not have to include all of them. However, you should be able to demonstrate the most crucial and interesting aspects of the analysis). Plus, a jupyter notebook detailing the process. Upload the two files as a single zip file on learnIT.
- Styling requirements (for the report). Font size (minimum) 11pt.
- Where to start: You can find a template to get started in the assignment on learnIT.
- Dataset: US Census data from https://github.com/zykls/folktables. We use data from individuals from California in 2018, as detailed in the template. The template also details which attributes we use as a feature vector. More details on the dataset can be found in the accompanying paper at https://arxiv.org/pdf/2108.04884.pdf or (Folktables Git)[https://github.com/socialfoundations/folktables].

Context:

- 1. We are going to work with two protected attributes: SEX and RAC1P (we are going to limit the datasets to Whites and African-Americans).
- 2. We have a binary target variable (Total Person's Income, aka PINCP_TRG), where the positive label stands for income above 25 000 USD.
- 3. We are going to use only **500 samples**.
- 4. Split your data into Train/Test before proceeding

Task 1 (Bias Analysis)

For this task, you will work with the training dataset

Task 1.1.: Data Collection and Representation

Let's look at the following attributes: AGEP, RAC1P, SEX, SCHL, CIT, COW. Do *not* use one hot encoded variables for **Task 1**.

- 1. Discuss sources of potential bias in the dataset and the selected features.
- 2. Cover the following aspect: Training Data (refer to **Lecture 5 Slide #56: How to handle bias?**).

Task 1.2.: Proxies

Look at the relationships between SEX vs. AGEP, RAC1P, PINCP (or PINCP_TRG), CIT, COW, MAR, and WKHP.

- 1. Look at feature distributions if you split them by SEX groups (for Males and Females, separately). Do you see any potential sources of bias? Provide arguments.
- 2. Look at the correlations between SEX and other variables.
- 3. Cover the following aspect: Proxies (refer to Lecture 5 Slide #56: How to handle bias?).
- 4. Supplement your answer with several visualisations. e.g. distributions of variables per protected group (*you do not have to provide all of them, but the ones you find interesting*).
- 5. When discussing correlations, do not forget to use the correct metric (e.g. continuous-categorical features etc.). You can use dython.nominal.associations and seaborn.heatmap.

Note: While discussing bias, use definitions/terms described in A Survey on Bias and Fairness in Machine Learning and Social Data: Biases, Methodological Pitfalls, and Ethical Boundaries (see Lecture 5: Reading Materials).

Task 2 (Model & Data Debiasing)

Now we will train a model to predict the income of a person based on the attributes we have at hand. We want to have a model with high predictive performance, but we also want to make sure that our model does not discriminate against any protected groups.

Task 2.1.: Data

- 1. Convert categorical to one-hot encoding.
- 2. Remove redundant categorical columns (as you have done in Lecture 6).
- 3. Remove protected attributes from the data (keep it aside).

Task 2.2.: Baseline Model

- 1. Build your own implementation of the Logistic Regression with L2-penalty (aka Ridge Regression).
 - Do not forget to add the column of ones for the intercept, β_0 (when calculating cost and/or gradient).
 - Do not penalise β_0 (when calculating L2-penalty).
 - You can use approx_grad=True or your implementation of compute_grad.
- 2. Use Cross-Validation to find the most optimal value for L2-penalty (you should implement it yourself).
- 3. Evaluate the overall performance of the final model on the Test Set (use appropriate metrics) + report uncertainty.
- 4. Look at the fairness metric associated with each SEX and RAC1P group. Are there any discrepancies?

Task 2.3.: Model with the Fair Penalty

- 1. Add Individual Fairness Penalty to your baseline model (refer to Lecture 5 Exercises).
 - Refer to the description in the paper
 - Use the L2-penalty coefficient from Task 2.2.
 - Do not forget to add the column of ones for the intercept, β_0 .
 - Do not penalise β_0 (when calculating L2-penalty).
 - Use approx_grad=True to approximate the gradient.
 - **Remember** that you have two protected features! Thus, you need to add one fairness constraint per feature.
- 2. Plot Pareto Curve by varying $\lambda = [1e-3, 5e-3, 1e-2, 5e-2, 0.1, 1]$, evaluate the performance of the model (using your favourite metric). Plot a curve for each group of protected attributes (i.e. 4 curves). What happens as we increase the penalty? Is there a point where all groups get similar performance metric values?
- 3. Set $\lambda=0.1$ and evaluate the overall performance of the final model on the Test Set (report uncertainty). Use the same metric as you used in **Task 2.2**.
- 4. Set $\lambda=0.1$ and look at the fairness metric associated with each SEX and RAC1P group. What do you see (compare results to the baseline model)?

Task 2.4.: Fair PCA

We are going to implement the method from Efficient fair PCA for fair representation learning. Here, we will use dimensionality reduction to remove any existing proxies associated with the protected features (refer to *Lecture 6 Exercises*).

Note: Some python functions output significance associated with the correlation. Ignore it throughout **Task 2.4**.

- 1. Use Standard PCA on non-protected features.
 - Remember to normalise data before applying Fair PCA or Standard PCA.
 - Use $N_{components} = N_{features} N_{protected\ groups}$, you have 4 protected groups (Males, Females, Whites and African-Americans).
 - Look at the correlations between the new dimensions and original protected features (use either *Pearson*'s or *Spearman*'s coefficient). What do you see?
- 2. Project your test data with Standard PCA, then project it back into the original space.
 - Note: sklearn implementation of PCA has a method called inverse_transform
 - Calculate the reconstruction error (e.g. mean absolute error) for each sample
 - Look at the reconstruction error per each protected group. What do you see?
- Implement Fair PCA (refer to Lecture 7 Exercises) and apply it to non-protected features.
 - Refer to Algorithm 1 in the paper
 - Remember to normalise data before applying Fair PCA + remember to remove mean from the protected attributes.
 - Use $N_{components} = N_{features} N_{protected\ groups}$, you have 4 protected groups (Males, Females, Whites and African-Americans).
 - Look at the correlations between the new dimensions and original protected features. How do results compare to the Standard PCA?
- 4. Project your test data with Fair PCA, then project it back into the original space.
 - Calculate the reconstruction error (e.g. mean absolute error) for each sample.
 - Look at the reconstruction error per each protected group. What do you see? Are there any differences compared to the Standard PCA?

Tips:

- 1. X @ U stands for matrix multiplication in python
- 2. Xp @ U.T can be used to reconstruct your data

Task 2.5: Logistic Regression and Fair PCA

- 1. Fit a Logistic Regression (your implementation) to the debiased data (via Fair PCA).
 - Do not use L2-penalisation
 - Do not forget to add the column of ones for the intercept, β_0 .
- 2. Evaluate the overall performance of the final model on the Test Set (report uncertainty).
- 3. Look at the fairness metric associated with each SEX and RAC1P group. Are there any discrepancies?

Task 3 (Robustness and Evaluation)

Task 3.1.: Model Robustness

Let's assume you decided to sell your model to the Bank. The Bank told you it wants to infer how much money people earn before they become clients (so that they can recommend personalised services to clients). Using your knowledge from Lecture 8, discuss the following:

- 1. Mention 2 things you would do to ensure that your model is *reliable*.
- 2. Mention 2 things you would do to ensure that your model is *robust*.
- 3. Mention 2 things you would do to report your results

Note: To answer these questions, refer to How to avoid machine learning pitfalls (see *Lecture 8: Reading Materials*).

Task 3.2.: Evaluation of the models

- Given the outcome of your study, which classifier is most suited for the prediction task under predictive performance and fairness considerations (for this particular dataset)?
- Name two advantages and disadvantages of each method you used (i.e. simply dropping the protected attributes, fair regression, and fair PCA).

Checklist

We will add the checklist by the end of the week.
